

## Definition

A *nondeterministic finite automata*  $N = (Q, \Sigma, \delta, q_0, F)$  is a list where  $Q$  and  $\Sigma$  are finite sets,  $\delta : Q \times \Sigma \rightarrow \mathcal{P}(Q)$ ,  $q_0 \in Q$  and  $F \subset Q$ . A *nondeterministic finite automata with empty moves*  $N = (Q, \Sigma, \delta, q_0, F)$  is a list where  $Q$  and  $\Sigma$  are finite sets,  $\delta : Q \times (\Sigma \cup \{\emptyset\}) \rightarrow \mathcal{P}(Q)$ ,  $q_0 \in Q$  and  $F \subset Q$ .

As with finite automata, we call  $Q$  the *states*,  $\Sigma$  the *alphabet*,  $\delta$  the *transition function*,  $q_0$  the *start state*, and  $F$  the *accept states* (or *final states*). An input  $u \in \text{str}(\Sigma)$  results in a state sequence  $x \in \text{str}(Q)$  with  $x_1 = q_0$  and  $x_{i+1} = \delta(x_i, u_i)$  for  $i = 1, \dots, |u|$ .

## Main result

For any automata  $M$ , there exists a nondeterministic finite automata  $N$  such that  $N$  accepts the same languages as  $M$ .<sup>1</sup> For this reason, a language is regular if and only if some nondeterministic finite automaton accepts it.
