

EMPTY SET

Why

Can a set have no elements?

Definition

Sure. A set exists by the principle of existence (see *Sets*); denote it by A . Specify elements (see *Set Specification*) of any set that exists using the universally false statement $x \neq x$. We denote that set by $\{x \in A \mid x \neq x\}$. It has no elements. In other words, $(\forall x)(x \notin A)$. The principle of extension (see *Set Equality*) says that the set obtained is unique (contradiction).¹

Definition 1 (Empty Set). We call the unique set with no elements *the empty set*.

ℒNotation

We denote the empty set by \emptyset . In other words, in all future accounts (see *Accounts*), there are two implicit lines. First, “**name** \emptyset ” and second “**have** $(\forall x)(x \notin \emptyset)$ ”.

Properties

It is immediate from our definition of the empty set and of the definition of inclusion (see *Set Inclusion*) that the empty set is included in every set (including itself).

Proposition 1. $(\forall A)(\emptyset \subset A)$

¹This account will be expanded in the next edition.

Proof. Suppose toward contradiction that $\emptyset \notin A$. Then there exists $y \in \emptyset$ such that $y \notin A$. But this is impossible, since $(\forall x)(x \notin \emptyset)$. \square
