

## OPERATIONS

### Why

We want to “combine” elements of a set.

### Definition

Let  $A$  be a non-empty set. An *operation* on  $A$  is a function from ordered pairs of elements of the set to the same set. Operations *combine* elements. We *operate* on ordered pairs.

### Notation

Let  $A$  be a set and  $g : A \times A \rightarrow A$ . We tend to forego the notation  $g(a, b)$  and write  $a g b$  instead. We call this *infix notation*.

Using lower case latin letters for elements and for operations confuses, so we tend to use special symbols for operations. For example,  $+$ ,  $-$ ,  $\cdot$ ,  $\circ$ , and  $\star$ .

Let  $A$  be a non-empty set and  $+$  :  $A \times A \rightarrow A$  be an operation on  $A$ . According to the above paragraph, we tend to write  $a + b$  for the result of applying  $+$  to  $(a, b)$ .

### Example

A first example of an operation is if we consider the set  $A$  as the power set of some set  $X$ . Then the pair union (see Pair Unions) is an operation. For if  $E \in \mathcal{P}(X)$  and  $F \in \mathcal{P}(X)$  then  $E \cup F \in \mathcal{P}(X)$  and so  $\cup$  can be viewed as an operation on  $\mathcal{P}(X)$ .

## Properties

Recall that  $\cup$  has several nice properties. For one  $A \cup B = B \cup A$  and  $(A \cup B) \cup C = A \cup (B \cup C)$ .

An operation with the first property, that the ordered pair  $(A, B)$  and  $(B, A)$  have the same result is called *commutative*. An operation with the second property, that when given three objects the order in which we operate does not matter is called *associative*.
