

Multivariate Normal Maximum Likelihood

1 Why

What of the generalization to a multivariate normal.

2 Result

Proposition 1. *Let (x^1, \dots, x^n) be a dataset in \mathbf{R}^d . Let f be a multivariate normal density with mean*

$$\frac{1}{n} \sum_{k=1}^d x^k$$

and covariance

$$\frac{1}{n} \sum_{k=1}^n \left(x^k - \frac{1}{n} \sum_{k=1}^n x^k \right) \left(x^k - \frac{1}{n} \sum_{k=1}^n x^k \right)^\top.$$

Then f is a maximum likelihood multivariate normal density.

Proof. We express the log likelihood

$$\sum_{k=1}^n -\frac{1}{2} (x^k - \mu)^\top \Sigma^{-1} (x^k - \mu) - \frac{1}{2} \log(2\pi)^d - \frac{1}{2} \log \mathbf{det} \Sigma$$

Let $P = \Sigma^{-1}$. The $\log \mathbf{det} \Sigma$ is $\log \mathbf{det} P^{-1}$ is $\log (\mathbf{det} P)^{-1}$ is $-\log \mathbf{det} P$. Use matrix calculus to get

$$\frac{\partial \ell}{\partial P} = \sum_{k=1}^n (x^k - \mu)(x^k - \mu)^\top - P^{-1}.$$

□

We call these two objects the *maximum likelihood mean* and *maximum likelihood covariance* of the dataset.
