
Why

We generalize the algebraic structure of addition and multiplication over the rationals.

Definition

A *field* is a ring $(R, +, \cdot)$ for which $\cdot$ is commutative (i.e., $ab = ba$ for all $a, b \in R$) and $\cdot$ has inverses for all elements except 0. In this case, we refer to *field addition* and *field multiplication*.

Notation

Since our guiding example is the set of rationals $\mathbf{Q}$ with addition and multiplication defined in the usual manner, and we use a bold font for $\mathbf{Q}$, we tend to denote an arbitrary field by $\mathbf{F}$, a mnemonic for "field."

Field operations

Along with field addition and field multiplication, we call the function which takes an element of a field to its additive inverse and the function which takes an element of a field to its multiplicative inverse the *field operations*.
