

## Inductors

## 1 Why

We want to talk about learning associations between perceptions in time or space.

## 2 Definition

An *inductor* is a function mapping a dataset of records in a cartesian product of two sets to a function between the two sets. We call the first set the *precepts* and the second set the *postcepts*. We call a function from the precepts to the postcepts a *predictor*. We call the result of a precept under a predictor a *prediction*. An inductor maps datasets to predictors.

## 2.1 Notation

We introduce no new notation, but rather express the new concepts in the old notation. Let A and B be non-empty sets. Let D be a dataset in  $A \times B$ . Let  $g: A \to B$ , a predictor, which makes prediction g(a) on precept  $a \in A$ . Let  $f: (A \times B)^n \to (A \to B)$ , an inductor. Then f(D) is the predictor which the inductor associates with dataset D.
