

## CORRELATION

# Why

### TODO

#### Definition

The *correlation* between two integrable real-valued random variables with non-zero variance is the quotient of their covariance with the product of their standard deviations.

Two integrable real-valued random variables are *uncorrelated* if their covariance is zero. We can speak of uncorrelated random variables who have zero variance, although in this case their correlation is undefined.

#### Notation

Let f and g be two integrable real-valued random variables with fg integrable. Denote the correlation of f with g by  $\mathbf{cor}(f,g)$ . We defined it:

$$\mathbf{cor}(f,g) = \frac{\mathbf{cov}(f,g)}{\mathsf{std}\,f\,\mathsf{std}\,g}.$$
