

## **PIVOTED ROW REDUCTIONS**

## Why

We want to modify ordinary row reduction to handle the case in which a pivot is zero by selecting another suitable pivot.

## Example

Let  $A \in \mathbb{R}^{5\times 5}$ . If  $A_{11} \neq 0$ , we may subtract multiples of row 1 from row 2, ..., 5 to eliminate variable  $x_1$  from those equations. If A reduces to  $C \in \mathbb{R}^{5\times 5}$  and  $C_{22} \neq 0$ , then step 2 moves from

What if  $C_{22} = 0$ ? In this case suppose we pick a different row. For example, if  $C_{42} \neq 0$  we can move from

Alternatively, we could introduce zeros in column 3 rather than column 2. For example, if we pick the pivot  $C_{43}$  we move from

We can choose any nonzero entry in  $C_{k:m,k:m}$  as the pivot.

Suppose we pick pivot  $C_{st} \neq 0$  for  $k \leq s, t \leq m$ . Define  $\tilde{C}$  by swapping row s of C with row k of C and column t of C

with column k of C. Then  $\tilde{C}_{kk} = C_{st} \neq 0$  and there exists an ordinary row reduction for  $\tilde{C}$ . We call this reduction of  $(\tilde{C}, \tilde{d})$  a pivoted row reduction of C or the st-reduction of C.

If all remaining pivots are zero, then there is no viable pivot. In this case, at least one variable is free and we do not have a unique solution. For convenience, in this case, we still call the system an *st*-reduction of itself.

## Definition

At step k of ordinary elimination, multiples of row k are subtracted from rows k + 1, ..., m to introduce zeros in entry k of the rows. If we denote the matrix at the beginning of that step by X, then row k of X, column k of X and especially the pivot  $X_{kk}$  play a role. Ordinarily, we subtract from every entry in the submatrix  $X_{k+1:m,k:m}$  the product of a number in row k and a number in column k, divided by the pivot  $X_{kk}$ . Generally, however, we can choose as pivot any nonzero entry of  $X_{k:m,k:m}$ .

An m-variable system (A, b) is pivot reducible (or reducible) if there exists a sequence of systems  $S_1, \ldots, S_{m-1}$  so that  $S_1$  is a reduction of (A, b) and  $S_i$  is a reduction of  $S_{i-1}$  for  $i = 1, \ldots, m-1$ . We call  $S_{m-1}$  the final reduction (or reduction) of (A, b). An immediate consequence of our definition is

Proposition 1. All systems are reducible.
