

MINIMUM MEAN SQUARED ERROR ESTIMATOR

Why

What is the best estimator for a real-value random variable if we consider the squared loss.

Definition

We want to estimate a random variable $x : \Omega \to \mathbb{R}^n$ from a random variable $y : \Omega \to \mathbb{R}^n$ using an estimator $\phi : \mathbb{R}^m \to \mathbb{R}^n$.

Proposition 1. The mmse estimator is the conditional mean.

Let $x: \Omega \to \mathbb{R}^n$ and $y: \Omega \to \mathbb{R}^m$. A minimum mean squared error estimator or MMSE estimator or least square estimator for x given y is an estimator $f: \mathbb{R}^m \to \mathbb{R}^n$ which minimizes $\mathbf{E} || f(x) - y ||^2$.
