

#### PROBABILISTIC MODELS

# Why

We have a space X and a family of probability measures  $\mathcal{P}$  on this space. Assume  $x \in X$  drawn from a fixed, unknown measure  $P \in \mathcal{P}$ . Given x, how should we guess P?

## Definition

A probabilistic model (or statistical model, parametric statistical model, statistical experiment) is a family of probability measures over the same measurable space  $(X, \mathcal{F})$ . Call the index set the parameter set or set of parameters. The set X is called the sample space. A statistic is any function on the sample space.

## Notation

Let  $(X, \mathcal{F})$  denote a measurable space. We usually denote the parameter by  $\Theta$ , and denote the family

$$\mathcal{P} = \{ \boldsymbol{\mathsf{P}}_{\boldsymbol{\theta}} : \mathcal{F} \rightarrow [0,1] \mid \boldsymbol{\mathsf{P}}_{\boldsymbol{\theta}} \text{ a measure}, \boldsymbol{\theta} \in \boldsymbol{\Theta} \}.$$

Often  $\Theta \subset \mathbf{R}^d$ .

# Example: coin flips

The usual model for n flips of a coin takes  $X = \{0,1\}^n$ , the set of binary n-tuples. For  $\theta \in [0,1]$ , a distribution  $p_{\theta}(x) = \theta^t (1-\theta)^{n-t}$  where  $t = t(x) = x_1 + \cdots + x_n$  is defined on X. A probability measure  $\mathbf{P}_{\theta}$  is defined on  $\mathcal{P}(X)$  in the the usual way. Thus, the probabilistic model is  $\{\mathbf{P}_{\theta} \mid \theta \in [0,1]\}$ . Given x, we are asked to guess  $\theta$ .

## **Decisions**

A decision procedure (estimator, statistical procedure) is a measurable function  $A: \mathcal{X} \to \mathcal{A}$  where  $\mathcal{A}$  is a set, called the actions or decisions. Often  $\mathcal{A} = \Theta$ , in which case A(x) givens an estimate of  $\theta$ , which we denote  $\hat{\theta}(x)$ .

# Judging decisions

Given a loss function  $L: \mathcal{A} \times \Theta \to \bar{\mathbf{R}}$ , the risk of A is

$$R(A, \theta) = \mathbf{E}L(A(x), \theta).$$
