

## SUPERVISED LEARNING ALGORITHMS

## Why

We sometimes use special language for a function inductor, which alludes to its similarities with "learning."

## **Definition**

Let X and Y be sets and let  $\{G_n : (X \times Y)^n \to \mathcal{P}(X \times Y)\}_{n \in \mathbb{N}}$  be a family of functional inductors. A predictor can be used to "guess" inputs which do not necessarily appear in the dataset. For this reason, some authors call an inductor (or family of inductors) a learner or learning algorithm. In accordance with this usage, they refer to the argument of an inductor as the training data or training dataset or training set. As with our terminology dataset, the word "set", however, may mislead since since we are speaking of a sequence.

It is common to refer to the construction a predictor from a dataset a *learning problem*. In this case, the learning problem is said to be *supervised learning*. By supervision, we mean to indicate that we have the outputs corresponding to the inputs. In line with this usage, the outputs are often called *labels* and the labels are said "to provide supervision."
