

## Nonnegative Integrals

## Why

We want to define area under an extended real function. We use the infinite process to approximate the area under a nonnegative extended real function using simple functions.

## Definition

Consider a measure space.

The *integral* of a measurable nonnegative function is the supremum of integrals over nonnegative simple functions pointwise less than or equal to the function.

## Notation

Let  $(X, \mathcal{A}, \mu)$  be a measure space. Let  $f: X \to [0, \infty]$  be measurable. We denote the integral of f with respect to the measure  $\mu$  by  $\int f d\mu$ . We defined:

$$\int f d\mu = \sup \biggl\{ \int g d\mu \ \bigg| \ g \in \mathop{\rm SF}_+(X) \text{ and } g \leq f \biggr\}.$$
