

SET RINGS

Definition

A set ring (or Boolean set ring, ring of sets, Boolean ring of sets) is a nonempty set of sets R such that if

$$E \in R$$
 and $F \in R$

then

$$E \cup F \in R$$
 and $E - F \in R$.

In other words, a ring is a nonemptyset of sets which is closed under unionsand differences.

Every ring contains the empty set, for if $E \in R$, then $E - E = \emptyset \in R$.

Also, since

$$E - F = (E \cup F) - F,$$

every nonempty set that is closed under unions and *proper* differences is a ring.
