

## POLYNOMIAL REGRESSORS

## Why

A simple example of an embedding.<sup>1</sup>

## Definition

Fix  $d \in \mathbf{N}$ . A polynomial feature map of degree d is a function  $\phi : \mathbf{R} \to \mathbf{R}^d$  with

$$\phi(x) = \begin{pmatrix} 1 & x^2 & \cdots & x^d \end{pmatrix}^\top.$$

For  $x \in \mathbf{R}$ , we call  $\phi(x)$  the polynomial embedding of x.

A polynomial regressor is a least squares linear predictor using a polynomial feature embedding (of any degree, but to be precise one must specify the degree). The task of constructing a linear predictor is often referred to as polynomial regression.

Given a dataset of paired records  $(x^1,y^1),\ldots,(x^2,y^2)\in \mathbf{R}^2$ , one can construct a predictor  $g:\mathbf{R}\to\mathbf{R}$  for y by embedding the dataset  $(\phi(x^1),\ldots,\phi(x^n))$  and finding the least squares linear regressor  $f:\mathbf{R}^d\to\mathbf{R}$  for y. One defines the predictor  $g:\mathbf{R}\to\mathbf{R}$  by  $g(\phi(x))$ .
