

## WEIGHTED NORMS

## Definition

**Proposition 1.** Let W be a positive semidefinite n by n matrix. Then  $g: \mathbb{R}^n \to \mathbb{R}$  defined by  $g(x) = \sqrt{x^\top W x}$  is a norm on  $\mathbb{R}^n$ .

## Notation

Let  $W \in \mathbf{R}^{n \times n}$ , positive semidefinite. Then we denote the norm corresponding to W by  $\|\cdot\|_W$ . So then, the norm of a vector  $x \in \mathbf{R}^n$  is  $\|x\|_w$ . Notice that  $\|x\|_W = \|W^{1/2}x\|_2$ .

## Visualization

1

We can compare the Euclidean norm on  ${\sf R}^2$  with the weighted norm given by

$$W = \begin{pmatrix} 2 & 1 \\ 1 & 4 \end{pmatrix}$$

 $<sup>^{1}</sup>$ Future editions will visualize these norms as function on  $\mathbb{R}^{2}$ , via contour plots.
