

## NORMAL MAXIMUM LIKELIHOOD

## Why

We want to select a normal density which summarizes well a dataset.

## **Formulation**

Let  $D = (x^1, ..., x^n)$  be a dataset in **R**. We want to select a density from among normal densities, which require specifying a mean and covariance.

Following the principle of maximum likelihood, we want to solve

$$\begin{array}{ll} & \text{find} & \mu,\sigma \in \mathsf{R} \\ & \text{to maximize} & \prod_{k=1}^n \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{1}{2}\left(\frac{x^k-\mu}{\sigma}\right)^2\right) \\ & \text{subject to} & \sigma > 0 \end{array}$$

We call a solution to the above problem a maximum likelihood normal density with respect to the dataset.

## Solution

Proposition 1. Let  $(x^1, \ldots, x^n)$  be a dataset in  $\mathbb{R}$ . Let f be a normal density with mean

$$\frac{1}{n} \sum_{k=1}^{n} x^k$$

and covariance

$$\frac{1}{n}\sum_{k=1}^{n}\left(x^{k}-\frac{1}{n}\sum_{k=1}^{n}x^{k}\right)^{2}$$
.

Then f is a maximum likelihood normal density.

*Proof.* Every normal density has two parameters: the mean and the covariance. If the likelihood of one normal is less than or equal to the likelihood of another, then so is are their log likelihoods. Let f be a normal density with parameter  $\mu$  and  $\sigma^2$ . We express the log likelihood of f by

$$\sum_{k=1}^{n} \left( \frac{1}{2\sigma^2} (x^k - \mu)^2 - \frac{1}{2} \log 2\pi \sigma^2 \right)$$

The partial derivative of the log likelihood with respect to the mean  $(\partial_{\mu}\ell): \mathbb{R}^2 \to \mathbb{R}$  is

$$(\partial_{\mu}\ell)(\mu,\sigma^2) = -\sum_{k=1}^{n} \frac{1}{\sigma^2}(x-\mu)$$

and with respect to the covariance  $(\partial_{\sigma^2}\ell): \mathbb{R}^2 \to \mathbb{R}$  is

$$(\partial_{\sigma^2}\ell)(\mu,\sigma^2) = \left(\frac{-1}{2(\sigma^2)^2} \sum_{k=1}^n (x^k - \mu)^2\right) - \frac{1}{2\sigma^2}$$

We are interested in finding  $\mu_0 \in \mathbf{R}$  and  $\sigma_0^2 > 0$ , at which  $\partial_{\mu}\ell(\mu_0, \sigma_0^2) = 0$  and  $\partial_{\sigma^2}\ell(\mu_0, \sigma_0^2) = 0$ . So we have two equations. First, notice that  $\partial_{\mu}\ell$  is zero if an only if its first argument (the mean) is  $\frac{1}{n} \sum_{k=1}^{n} x^k$ . Second, notice that for all  $\mu, \sigma^2, \partial_{\sigma^2}\ell$  is zero if and only if

$$\sigma^2 = \sum_{k=1}^{n} (x^k - \mu)^2.$$

So the pair

$$\left(\frac{1}{n}\sum_{k=1}^{k} x^k, \frac{1}{n}\sum_{k=1}^{n} (x_k - \frac{1}{n}\sum_{k=1}^{n} x^k)^2\right)$$

is a stationary point of  $\ell$ .
