

#### **FUNCTIONS**

# Why

We want a notion for a correspondence between two sets.

## **Definition**

A function (or mapping or map) f from a set X to a set Y is a relation (see Relations) whose domain is X and whose range is a subset of Y such that for each  $x \in X$ , there exists a unique  $y \in Y$  so that  $(x, y) \in f$ .

We call the unique  $y \in Y$  the result of the function at the argument x. We call Y the codomain. If the range is Y we say that f is a function from X onto Y (or f is surjective). If distinct elements of X are mapped to distinct elements of Y, we say that the function is one-to-one (or injective).

We say that the function *maps* (or *takes*) elements from the domain to the codomain. Since the word "function" and the verb "maps" connote activity, some authors refer to the set of ordered pairs as the *graph* of a function and avoid defining "function" in terms of sets.

### **Notation**

Let X and Y denote sets. We denote a function named f whose domain is X and whose codomain is Y by  $f: X \to Y$ . We read the notation aloud as "f from X to Y". We denote the set of all functions from X to Y (which is a subset of  $\mathcal{P}((X \times Y))$ ) by  $Y^X$ . A less standard but equally good notation is  $X \to Y$ , read

aloud as "A to B". Using the earlier notation, we denote that  $f \in (A \to B)$  by  $f : A \to B$ . We tend to denote function by lower case latin letters, especially f, g, and h. f is a mnemonic for function and g and h are nearby.

Let  $f: A \to B$ . For each element  $a \in A$ , we denote the result of applying f to a by f(a), read aloud "f of a." We sometimes drop the parentheses, and write the result as  $f_a$ , read aloud as "f sub a." Let  $g: A \times B \to C$ . We often write g(a,b) or  $g_{ab}$  instead of g((a,b)). We read g(a,b) aloud as "g of a and b". We read  $g_{ab}$  aloud as "g sub a b."

## **Examples**

If  $X \subset Y$ , the function  $\{(x,y) \in X \times Y \mid x=y\}$  is the inclusion function of X into Y. We often introduce such a function as "the function from X to Y defined by f(x) = y". We mean by this that f is a function and that we are specifying the appropriate ordered pairs using the statement, called argument-value notation. The inclusion function of X into X is called the identity function of X. If we view the identity function as a relation on X, it is the relation of equality on X.

The functions  $f:(X \times Y) \to X$  defined by f(x,y) = x is the pair projection of  $X \times Y$  ono X. Similarly  $g:(X \times Y) \to Y$  defined by g(x,y) = y is the pair projection of  $X \times Y$  onto Y. The identity function is one-to-one and onto, the inclusion functions are one-to-one but not always onto, and the pair projections are usually not one-to-one.
