

## Partial Derivatives

# Why

We want to talk about how a function of multiple real-valued arguments changes with respect to changes in its arguments.

### **Definition**

Consider a real-valued function on d-dimensional space. For  $i=1,\ldots,d$ , Fix a point x. consider the limit of a sequence of quotients of the difference of the result of that function at a point the consider the limit of a sequence of quotients of the value changed at component The partial derivative of the function with respect to the ith the function which maps d-dimensional vectors of real numbers to the limit of a seq of all of the quotient between the point to argument is the limit of the rate with a The partial derivative of a

Let 
$$f: \mathbf{R}^d \to \mathbf{R}$$
 For  $i = 1, ..., d$ , define Let  $g_i: \mathbf{R}^d \to \mathbf{R}$  by 
$$g_i(x) = \lim_{h \to 0} \frac{f(x + he_i) - f(x)}{h}$$

for each x

#### **Notation**

#### Gradient

The *gradient* of a multivariate function is the vector-valued function whose *i*th component is the partial derivative of the function with respect to its *i*th argument.

#### Notation

Let  $f: \mathbb{R}^n \to \mathbb{R}$ . The gradient of f is frequently denoted  $\nabla f$ . It is understood that  $(\nabla f) \in \mathbb{R}^d \to \mathbb{R}^d$ . An alternative notation is to use that similar for single derivatives and to denote the gradient (sometimes called derivative) of f by f' (assuming it exists). It is important to here note that although when  $g: \mathbb{R} \to \mathbb{R}$ ,  $g' \in (\mathbb{R} \to \mathbb{R})$ , (and so is another function from and to reals) when  $f: \mathbb{R}^d \to \mathbb{R}$ ,  $f' \in \mathbb{R}^d \to \mathbb{R}^d$ , and so is a vector-valued (not a real-valued) function.

There is (unfortunately) much notation for the individual partial derivatives; most of which we shall not (fortunately) have occasion to use in these sheets. One popular usage is the use of the  $\partial$  symbol, read aloud as "partial." For example, if  $f: \mathbb{R}^2 \to \mathbb{R}$  is a function of two arguments, each being referred to as x and y, then  $\partial_x f$  denotes the partial derivative of f with respect to x and  $\partial_y f$  denotes the partial derivative of f with respect to y. It is understood that  $(\partial_x f) \in \mathbb{R}^d \to \mathbb{R}$ . and likewise for  $\partial_y f$ . Another popular usage is  $\partial f/\partial x$  for  $\partial_x f$  and  $\partial f/\partial y$  for  $\partial_y f$ . We will almost exclusively prefer the gradient notation.
