

### PROBABILISTIC CLASSIFIERS

# Why

Since our predictions are often uncertain, we can use the language of probability distributions to characterize them.<sup>1</sup>

## Definition

Denote the set of probability distributions on a set X by  $\Delta(X)$ .

A probabilistic classifier  $G: A \to \Delta(B)$  is a function from inputs A to probability distributions over the classes B.

Given an input a, the *prediction* of G on a is a probability distribution  $\hat{p}_a = G(a)$  on B.

### Point classifier as probabilistic classifier

Given a point classifier  $f: A \to B$ , we can define a probabilistic classifier  $G: A \to \Delta(B)$  corresponding to f by

$$\hat{p}_a(b) = \begin{cases} 1 & \text{if } f(a) = b \\ 0 & \text{otherwise.} \end{cases}$$

where  $\hat{p}_a = G(a)$ .

#### Probabilistic classifier from point classifier

On the other hand, given probabilistic classifier  $G: A \to \Delta(B)$ , we can define a point classifier  $f: A \to B$  by

$$f(a) = \operatorname*{argmax}_{b \in B} \hat{p}_a(v)$$

We call f the maximum likelihood classifier corresponding to G. If there are ties, we can order the (finite) set B arbitrarily, and break ties accordingly.

We can extend this idea, and define a list classifier by sorting the outputs by their probability, from largest to smallest.
