

Correlation

1 Why

TODO

2 Definition

The *correlation* between two integrable real-valued random variables with non-zero variance is the quotient of their covariance with the product of their standard deviations.

Two integrable real-valued random variables are *uncorrelated* if their covariance is zero. We can speak of uncorrelated random variables who have zero variance, although in this case their correlation is undefined.

2.1 Notation

Let f and g be two integrable real-valued random variables with fg integrable. Denote the correlation of f with g by $\mathbf{cor}(f,g)$. We defined it:

$$\operatorname{cor}(f,g) = \frac{\operatorname{cov}(f,g)}{\operatorname{std} f \operatorname{std} g}.$$
