

## **EIGENVALUES AND DEFINITENESS**

## Why

Can we characterize positive (semi-)definite matrices in terms of their eigenvalues?

## Main Result

Using eigenvalue decompositions, we can answer in the affirmative.

**Proposition 1.** Suppose  $A \in \mathbf{S}^d$  has smallest eigenvalue  $\lambda_{\min}(A)$ . Then

$$\begin{split} A \in \mathbf{S}_{+}^{d} & \longleftrightarrow \quad \lambda_{\min}(A) \geq 0 \\ & \longleftrightarrow \quad \operatorname{tr} AB \geq 0 \ \textit{for all } B \in \mathbf{S}_{+}^{d}. \end{split}$$

and

$$A \in \mathbf{S}_{++}^d \quad \longleftrightarrow \quad \lambda_{\min}(A) > 0$$
 
$$\longleftrightarrow \quad \operatorname{tr} AB > 0 \ \textit{for all nonzero} \ B \in \mathbf{S}_{++}^d.$$
