

Symmetric Lower Upper Triangular Factorizations

Why

What of lower upper triangular factorizations when the system is symmetric?

Definition

A symmetric lower upper triangular factorization of A is a pair of matrices $(L \in \mathbf{R}^{m \times m}, U \in \mathbf{R}^{m \times m})$ where L is unit lower triangular, U is upper triangular and A = LU.

$$A = LL^{\top}$$
.

Other terminology includes lower upper triangular factorization, LU decomposition, LU factorization. Define $R = L^{\top}$, then

$$A = R^{\top} R.$$

Let $A \in \mathbf{R}^{n \times n}$. Then the ordinary row reduction of A is a matrix U which is upper triangular.be symmetric. A lower upper triangular decomposition A is a pair of matrices (L, L^{\top}) where $L \in \mathbf{R}^{n \times n}$ is lower triangular, has nonnegative real diagonal entries, and satisfies

$$A = LL^{\top}.$$

Other terminology includes lower upper triangular factorization, LU decomposition, LU factorization. Define $R = L^{\top}$, then

$$A = R^{\top} R$$
.

Basic properties

Proposition 1. Let $A \in \mathbb{R}^{m \times m}$ be positive definite. Then there exists unique lower triangular matrix $L \in \mathbb{R}^{n \times n}$ so that

$$A = LL^{\top}.$$

So, in the case that A is positive definite, a lower upper triangular decomposition exists and is unique. Therefore we refer to it as the upper

lower triangular decomposition of A. It is also known (universally) as the Cholesky decomposition or Cholesky factorization of A.

Proposition 2. If A is positive semidefinite, there exists a permutation matrix P for which there is a unique L so that

$$P^{\top}AP = LL^{\top}.$$

This second proposition says that there is a unique Cholesky decomposition for a particular permutation (or pivoting) of A.

Unitriangular form

A lower diagonal upper decomposition (or lower diagonal upper factorization) of a matrix A a sequence (L, D, L^{\top}) where $L \in \mathbf{R}^{n \times n}$ is unit lower triangular, $D \in \mathbf{R}^{n \times n}$ is diagonal with real nonnegative entries and

$$A = LDL^{\top}$$
.

Other terminology includes LDL decomposition, LDL factorization, LDU factorization, LDU decomposition.

If $(L \in \mathbf{R}^{n \times n}, D \in \mathbf{R}^{n \times n}, L^{\top})$ is a LDU decomposition of $A \in \mathbf{R}^{n \times n}$, then $(LD^{1/2}A = LDL^{\top})$ then $(\tilde{L}D^{1/2}, D^{1/2}L^{\top})$ is a LU decomposition. Conversely, if (B, B^{\top}) is a LU decomposition and S is the diagonal matrix satisfying $S_{ii} = B_{ii}$ for $i = 1, \ldots, n$, then $(BS^{-1}, S^2, S^{-1}B^{\top})$ is a LDU decomposition of A.
