

PRODUCT DISTRIBUTIONS

Why

How do we get a joint probability distribution function from marginals?¹

Definition

The product distribution of a sequence $p_1, \ldots, p_n : A_i \to [0,1]$ of distributions is the function $p: \prod_i A_i \to [0,1]$ defined by

$$p(x) = \prod_{i=1}^{n} p_i(x_i).$$

Proposition 1. Let $p_i: A_i \to [0,1]$ be probability distributions. Then the product distribution of p_1, \ldots, p_n is a probability distribution with marginals p_1, \ldots, p_n .²

Example: fair coin repeated flips

Suppose we want to model a coin flipped n times. Supposing the coin is fair (see Probability Distributions) we might use our probability distribution $p:\{0,1\} \to [0,1]$ which assigned $p(0)=p(1)=\frac{1}{2}$. Then the probability of obtaining a sequence of flips $x \in \{0,1\}$ is

$$p(x) = \prod_{x_i=1} p_i(1) \prod_{x_i=0} p_i(0).$$

Notice that if we know $p_i(1) = \rho_i$, then we know $p(0) = (1 - \rho_i)$ and so we can write the above as

$$p(x) = \prod_{x_i=1} \rho_i \prod_{x_i=0} (1 - \rho_i).$$
