

## REAL LENGTH IMPOSSIBLE

# Why

Given a subset of the real line, what is its length?

# Background

Let  $a, b \in R$  with  $a \leq b$ . The *length* of the closed interval of the real numbers [a, b] is b - a. The length is non-negative.

A family  $\{A_{\alpha}\}_{{\alpha}\in I}$  is disjoint if for  ${\alpha},{\beta}\in I, {\alpha}\neq {\beta}$ , then  $A_{\alpha}\cap A_{\beta}=\varnothing$ . A set A can be partioned into a family if there exists a disjoint family whose union is A. A set  $A\subset R$  is simple if it can be partitioned into a countable family whose members are closed intervals. The above discussion suggests that we should define the length of a simple set as the sum of the lengths of sets which parition it.

The above discussion suggests that if we wish to define a function length :  $2^R \to R \cup \{-\infty, \infty\}$ , we should ask that (1) length(A)  $\geq 0$ , (2) length([a, b]) = b - a, (3) for disjoint closed intervals  $\{A_n\}_{n \in \mathbb{N}}$ , length( $A_i$ ) =  $\sum_i \text{length}(A_i)$ , and (4) for all  $A \subset R$  and  $a \in R$ , length(A + x) = length(A).

## Converse

Define the equivalence relation  $\sim$  on R by by  $x \sim y$  if  $x \sim y \in Q$ 

## Notation

Let A be a set and  $A \subset A^*$ . We denote the subset algebra of A and A by (A, A), read aloud as "A, script A."

# **Properties**

Proposition 1. For any set A,  $2^A$  is a sigma algebra.

Proposition 2. The intersection of a family of sigma algebras is a sigma algebra.

## Generation

Proposition 3. Let A a set and  $\mathcal{B}$  a set of subsets. There is a unique smallest sigma algebra  $(A, \mathcal{A})$  with  $\mathcal{B} \subset \mathcal{A}$ .

We call the unique smallest sigma algebra containing B the generated sigma algebra of B.
