

# **OPTIMIZATION PROBLEMS**

# Why

We are frequently interested in finding minimizers of real functions.<sup>1</sup>

## Definition

An optimization problem is a pair  $(\mathcal{X}, f : \mathcal{X} \to \mathbf{R})$  in which  $\mathcal{X}$  is a nonempty set called the *constraint set* and f is called the *objective* (or *cost function*).

If  $\mathcal{X}$  is finite we call the optimization problem *discrete*. If  $\mathcal{X} \subset \mathbb{R}^d$  we call the optimization problem *continuous*.

We refer to all elements of the constraint set as feasible. We refer to an element  $x \in \mathcal{X}$  of the constraint set as optimal if  $f(x) = \inf_{z \in \mathcal{X}} f(z)$ . We also refer to optimal elements as solutions of the optimization problem.

It is common for f and  $\mathcal{X}$  to depend on some other, known, given objects. In this case, these objects are often called parameters or problem data.

#### Notation

We often write optimization problems as

minimize 
$$f(x)$$
  
subject to  $x \in \mathcal{X}$ .

In this case we call x the decision variable.

<sup>&</sup>lt;sup>1</sup>Future editions will modify and expand.

## **Extended reals**

It is common to let  $f: \mathcal{X} \to \overline{\mathbf{R}}$ , and allow there to exist  $x \in \mathcal{X}$  for which  $f(x) = \infty$ . This is a trick to embed further constraints in the objective.

## Maximization

If we have some function  $g: \mathcal{X} \to \bar{\mathbf{R}}$  that we wish to maximize, we can always convert it to an optimization problem by defining  $f: \mathcal{X} \to \bar{\mathbf{R}}$  by f(x) = -g(x). In this case g is often called a reward, utility or profit.

# **Solvers**

Let  $\mathcal{P} = \{(X_a, f_a : X_a \to \bar{\mathbf{R}})\}_{a \in A}$  be a family of optimization problems. A solver (or solution method or solution algorithm) for  $\mathcal{P}$  is a function  $S : A \to \mathcal{S}$  such that  $S_a$  is a solution of the problem  $(X_a, f_a)$ .

Loosely speaking, the difficulty of "solving" the optimization problem  $(\mathcal{X}, f)$  depends on the properties of  $\mathcal{X}$  and f and the problem "size". For example, when  $\mathcal{X} \subset \mathbb{R}^d$  the difficulty is related to the "dimension" d of  $x \in \mathcal{X}$ .
